Abstract: Traumatic dental injuries (TDIs) of permanent teeth occur frequently in children and young adults. Crown fractures and luxations are the most commonly occurring of all dental injuries. Proper diagnosis, treatment planning and followup are important for improving a favorable outcome. Guidelines should assist dentists and patients in decision making and for providing the best care effectively and efficiently. The International Association of Dental Traumatology (IADT) has developed a consensus statement after a review of the dental literature and group discussions. Experienced researchers and clinicians from various specialties were included in the group. In cases where the data did not appear conclusive, recommendations were based on the consensus opinion of the IADT board members. The quidelines represent the best current evidence based on literature search and professional opinion. The primary goal of these guidelines is to delineate an approach for the immediate or urgent care of TDIs. In this first article, the IADT Guidelines for management of fractures and luxations of permanent teeth will be presented. (Dental Traumatology 2012;28:2–12; doi: 10.1111/j.1600-9657.2011.01103.x) Accepted January 7, 2012.

\* Members of the Task Group.

Whenever referring to IADT Guidelines, the original article, (Dent Traumatol 2012;28:2-12) should always be used as reference.

Traumatic dental injuries (TDIs) occur with great frequency in preschool, school-age children, and young adults comprising 5% of all injuries for which people seek treatment (1, 2). A 12-year review of the literature reports that 25% of all school children experience dental trauma and 33% of adults have experienced trauma to the permanent dentition, with the majority of injuries occurring before age nineteen (3). Luxation injuries are the most common TDIs in the primary dentition, whereas crown fractures are more commonly reported for the permanent dentition (1, 4, 5) TDIs present a challenge to clinicians worldwide. Consequently, proper diagnosis, treatment planning and follow up are critical to assure a favorable outcome.

Guidelines, among other things, should assist dentists, other healthcare professionals, and patients in decision making. Also, they should be credible, readily understandable, and practical with the aim of delivering appropriate care as effectively and efficiently as possible.

The following guidelines by the International Association of Dental Traumatology (IADT) represent an updated set of guidelines based on the original guidelines published in 2007 (6-8). The update was accomplished by doing a review of the current dental literature using EMBASE, MEDLINE, and PUBMED searches from 1996 to 2011 as well as a search of the journal of Dental Traumatology from 2000 to 2011. Search words included tooth fractures, root fractures, tooth luxation, lateral luxation and permanent teeth, intruded permanent teeth, and luxated permanent teeth.

The primary goal of these guidelines is to delineate an approach for the immediate or urgent care of TDIs. It is understood that subsequent treatment may require secondary and tertiary interventions involving specialist consultations, services, and/or materials/methods not always available to the primary treating clinician.

The IADT published its first set of guidelines in 2001 and updated them in 2007 (6-13). As with the previous guidelines, the working group included experienced investigators and clinicians from various dental specialties and general practice. This revision represents the best evidence based on the available literature and expert professional judgment. In cases where the data did not appear conclusive, recommendations are based on the consensus opinion of the working group followed by review by the members of the IADT Board of Directors. It is understood that guidelines are to be applied with evaluation of the specific clinical circumstances, clinicians' judgment, and patients' characteristics, including but not limited to compliance, finances, and understanding of the immediate and long-term outcomes of treatment alternatives versus non-treatment. The IADT cannot and does not guarantee favorable outcomes from strict adherence to the Guidelines, but believe that their application can maximize the chances of a favorable outcome.

Guidelines undergo periodic updates. These 2012 Guidelines in this journal will appear in three parts: Part I: Fractures and luxations of permanent teeth Part II: Avulsion of permanent teeth Part III: Injuries in the primary dentition

Guidelines offer recommendations for diagnosis and treatment of specific TDIs; however, they do not provide the comprehensive nor detailed information found in textbooks, the scientific literature, and, most recently, the Dental Trauma Guide (DTG) that can be accessed on http://www.dentaltraumaguide.org. Additionally, the DTG, also available on the IADT's web page http://www.iadt-dentaltrauma.org, provides a visual and animated documentation of treatment procedures as well as estimations of prognosis for the various TDIs.

## General recommendations/considerations

## Clinical examination

Detailed description of protocols, methods, and documentation for clinical assessment of TDIs can be found in current textbooks (1, 14, 15).

## Radiographic examination

Several projections and angulations are routinely recommended, but the clinician should decide which radiographs are required for the individual. The following are suggested:

- Periapical radiograph with a 90° horizontal angle with central beam through the tooth in question.
- Occlusal view.
- Periapical radiograph with lateral angulations from the mesial or distal aspect of the tooth in question.

Emerging imaging modalities such as cone-beam computerized tomography (CBCT) provide enhanced visualization of TDIs, particularly root fractures and lateral luxations, monitoring of healing, and complications. Availability is limited, and its use not currently considered routine; however, specific information is available in the scientific literature (16, 17).

#### Splinting type and duration

Current evidence supports short-term, non-rigid splints for splinting of luxated, avulsed, and root-fractured teeth. While neither the specific type of splint nor the duration of splinting for root-fractured and luxated teeth are significantly related to healing outcomes, it is considered best practice to maintain the repositioned tooth in correct position, provide patient comfort and improved function (18, 19).

#### Use of antibiotics

There is limited evidence for use of systemic antibiotics in the management of luxation injuries and no evidence that antibiotic coverage improves outcomes for rootfractured teeth. Antibiotic use remains at the discretion of the clinician as TDI's are often accompanied by soft tissue and other associated injuries, which may require other surgical intervention. In addition, the patient's medical status may warrant antibiotic coverage (19, 20).

## Sensibility tests

Sensibility testing refers to tests (cold test and/or electric pulp test) attempting to determine the condition of the pulp. At the time of injury, sensibility tests frequently give no response indicating a transient lack of pulpal response. Therefore, at least two signs and symptoms are necessary to make the diagnosis of necrotic pulp. Regular follow up controls are required to make a pulpal diagnosis.

## Immature versus mature permanent teeth

Every effort should be made to preserve pulpal vitality in the immature permanent tooth to ensure continuous root development. The vast majority of TDIs occur in children and teenagers where loss of a tooth has lifetime consequences. The immature permanent tooth has considerable capacity for healing after traumatic pulp exposure, luxation injury, and root fractures. Pulp exposures secondary to TDIs are amenable to proven conservative pulp therapies that maintain vital pulp tissue and allow for continued root development (21-24). In addition, emerging therapies have demonstrated the ability to revascularize/regenerate vital tissue in canals of immature permanent teeth with necrotic pulps (25-30). Teeth frequently sustain a combination of several injuries. Studies have demonstrated that crown-fractured teeth with or without pulp exposure and associated luxation injury experience a greater frequency of pulp necrosis (31). The mature permanent tooth that sustains a severe TDI after which pulp necrosis is anticipated is amenable to preventive pulpectomy as root development is substantially completed.

# Pulp canal obliteration

Pulp canal obliteration (PCO) occurs more frequently in teeth with open apices which have suffered a severe luxation injury. It usually indicates ongoing pulpal vitality. Extrusion, intrusion, and lateral luxation injuries have high rates of PCO (32, 33) Subluxated and crownfractured teeth also may exhibit PCO, although with less frequency (34). Additionally, PCO is a common occurrence following root fractures (35, 36).

## Permanent teeth

1. Treatment guideli	nes for fractures of teet	h and alveolar bone	Follow-up procedures for fractures of teeth and alveolar bone <sup>1</sup>	Favorable and unfavorable outcomes include some, but not necessarily all, of the following		
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome
Infraction	An incomplete fracture (crack) of the enamel without loss of tooth structure     Not tender. If tenderness is observed evaluate, the tooth for a possible luxation injury or a root fracture	No radiographic abnormalities     Radiographs recommended: a periapical view. Additional radiographs are indicated if other signs or symptoms are present	• In case of marked infractions, etching and sealing with resin to prevent discoloration of the infraction lines; otherwise, no treatment is necessary	No follow up is generally needed for infraction injuries unless they are associated with a luxation injury or other fracture types	Asymptomatic     Positive response to pulp testing     Continuing root development in immature teeth	Symptomatic     Negative response to pulp testing     Signs of apical periodontitis     No continuing root development in immature teeth     Endodontic therapy appropriate for stage of root development is indicated
Enamel fracture	A complete fracture of the enamel     Loss of enamel. No visible sign of exposed dentin     Not tender. If tenderness is observed, evaluate the tooth for a possible luxation or root fracture injury     Normal mobility     Sensibility pulp test usually positive	visible	If the tooth fragment is available, it can be bonded to the tooth     Contouring or restoration with composite resin depending on the extent and location of the fracture	6-8 weeks C <sup>++</sup> 1 year C <sup>++</sup>	Asymptomatic     Positive response to pulp testing     Continuing root development in immature teeth     Continue to next evaluation	Symptomatic Negative response to pulp testing Signs of apical periodontitis No continuing root development in immature teeth Endodontic therapy appropriate for stage of root development is indicated

1. Treatment guidel	ines for fractures of tee	th and alveolar bone	Follow-up procedures for fractures of teeth and alveolar bone <sup>1</sup>	Favorable and unfavorable outcomes include some, but not necessarily all, o following		
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome
Enamel-dentin fracture	A fracture confined to enamel and dentin with loss of tooth structure, but not exposing the pulp     Percussion test: not tender. If tenderness is observed, evaluate the tooth for possible luxation or root fracture injury     Normal mobility     Sensibility pulp test usually positive	loss is visible Radiographs recommended: periapical, occlusal, and eccentric exposure to rule out tooth displacement or possible presence of root fracture Radiograph of lip or cheek lacerations to	If a tooth fragment is available, it can be bonded to the tooth. Otherwise, perform a provisional treatment by covering the exposed dentin with glass lonomer or a more permanent restoration using a bonding agent and composite resin, or other accepted dental restorative materials  If the exposed dentin is within 0.5 mm of the pulp (pink, no bleeding), place calcium hydroxide base and cover with a material such as a glass ionomer	6-8 weeks C <sup>++</sup> 1 year C <sup>++</sup>	Asymptomatic     Positive response to pulp testing     Continuing root development in immature teeth     Continue to next evaluation	Symptomatic     Negative response to pulp testing     Signs of apical periodontitis     No continuing rod development in immature teeth     Endodontic therapy appropriate for stage of root development is indicated
Enamel-dentin-pulp racture	A fracture involving enamel and dentin with loss of tooth structure and exposure of the pulp. Normal mobility Percussion test: not tender. If tenderness is observed, evaluate for possible luxation or root fracture injury Exposed pulp sensitive to stimuli	loss visible	<ul> <li>In young patients with immature, still developing teeth, it is advantageous to preserve pulp vitality by pulp capping or partial pulpotomy. Also, this treatment is the choice in young patients with completely formed teeth</li> <li>Calcium hydroxide is a suitable material to be placed on the pulp wound in such procedures</li> </ul>	6-8 weeks C <sup>++</sup> 1 year C <sup>++</sup>	Asymptomatic     Positive response to pulp testing     Continuing root development in immature teeth     Continue to next evaluation	Symptomatic     Negative responsive pulp testing     Signs of apical periodontitis     No continuing rodevelopment in immature teeth     Endodontic therapy appropriate for stage of root development is indicated

1. Treatment guide	ent guidelines for fractures of teeth and alveolar bone			Follow-up procedures for fractures of teeth and alveolar bone <sup>1</sup>	Favorable and unfavorable outcomes include some, but not necessarily all, of the following		
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome	
Crown-root fracture without pulp exposure	A fracture involving enamel, dentin, and cementum with loss of tooth structure, but not exposing the pulp     Crown fracture extending below gingival margin     Percussion test: tender     Coronal fragment mobile     Sensibility pulp test usually positive for apical fragment	Apical extension of fracture usually not visible     Radiographs recommended: periapical, occlusal, and eccentric exposures. They are recommended to detect fracture lines in the root	Emergency treatment  As an emergency treatment, a temporary stabilization of the loose segment to adjacent teeth can be performed until a definitive treatment plan is made  Non-emergency treatment alternatives Fragment removal only Removal of the coronal crown—root fragment and subsequent restoration of the apical fragment exposed above the gingival level Fragment removal and gingivectomy (sometimes ostectomy)  Removal of the coronal crown—root segment with subsequent endodontic treatment and restoration with a post-retained crown. This procedure should be preceded by a gingivectomy, and sometimes ostectomy with osteoplasty Orthodontic extrusion of apical fragment Removal of the coronal segment with subsequent endodontic treatment and orthodontic extrusion of the remaining root with sufficient length after extrusion to support a post-retained crown Surgical extrusion Removal of the mobile fractured fragment with subsequent surgical repositioning of the root in a more coronal position Root submergence Implant solution is planned Extraction Extraction with immediate or delayed implant-retained crown restoration or a conventional bridge. Extraction is inevitable in crown—root fractures with a severe apical extension, the extreme being a vertical fracture	6-8 weeks C++ 1 year C++	Asymptomatic     Positive response to pulp testing     Continuing root development in immature teeth     Continue to next evaluation	Symptomatic Negative response to pulp testing Signs of apical periodontitis No continuing root development in immature teeth Endodontic therapy appropriate for stage of root development is indicated	

Treatment guidelines for fractures of teeth and alveolar bone					Favorable and unfavorable outcon include some, but not necessarily of the following		
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome	
Crown-root fracture with pulp exposure	A fracture involving enamel, dentin, and cementum and exposing the pulp     Percussion test: tender     Coronal fragment mobile	Apical extension of fracture usually not visible     Radiographs recommended: periapical and occlusal exposure	Emergency treatment  As an emergency treatment a temporary stabilization of the loose segment to adjacent teeth  In patients with open apices, it is advantageous to preserve pulp vitality by a partial pulpotomy. This treatment is also the choice in young patients with completely formed teeth. Calcium hydroxide compounds are suitable pulp capping materials. In patients with mature apical development, root canal treatment can be the treatment of choice Non-Emergency Treatment Alternatives  Fragment removal and gingivectomy (sometimes ostectomy) Removal of the coronal fragment with subsequent endodontic treatment and restoration with a post-retained crown. This procedure should be preceded by a gingivectomy and sometimes ostectomy with osteoplasty. This treatment option is only indicated in crown-root fractures with palatal subgingival extension  Orthodontic extrusion of apical fragment Removal of the coronal segment with subsequent endodontic treatment and orthodontic extrusion of the remaining root with sufficient length after extrusion to support a post-retained crown  Surgical extrusion Removal of the mobile fractured fragment with subsequent surgical repositioning of the root in a more coronal position  Root submergence An implant solution is planned, the root fragment may be left in situ  Extraction Extraction is inevitable in very deep crown-root fractures, the extreme being a vertical fracture		Asymptomatic     Positive     response to     pulp testing     Continuing root     development     in immature     teeth     Continue to     next evaluation	Symptomatic Negative response to pulp testing Signs of apical periodontitis No continuing root development in immature teeth Endodontic therapy appropriate for stage of root development is indicated	

2. Treatment guide	ines for luxation injurie	s	Follow-up procedures for luxated permanent teeth	Favorable and unfavorable outcomes include some, but not necessarily all, of the following <sup>2</sup>		
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome
Root fracture	The coronal segment may be mobile and may be displaced The tooth may be tender to percussion Bleeding from the gingival sulcus may be noted Sensibility testing may give negative results initially, indicating transient or permanent neural damage Monitoring the status of the pulp is recommended Transient crown discoloration (red or gray) may occur	The fracture involves the root of the tooth and is in a horizontal or oblique plane Fractures that are in the horizontal plane can usually be detected in the regular periapical 90° angle film with the central beam through the tooth. This is usually the case with fractures in the cervical third of the root  If the plane of fracture is more oblique, which is common with apical third fractures, an occlusal view or radiographs with varying horizontal angles is more likely to demonstrate the fracture including those located in	Reposition, if displaced, the coronal segment of the tooth as soon as possible Check position radiographically Stabilize the tooth with a flexible splint for 4 weeks. If the root fracture is near the cervical area of the tooth, stabilization is beneficial for a longer period of time (up to 4 months) It is advisable to monitor healing for at least 1 year to determine pulpal status If pulp necrosis develops, root canal treatment of the coronal tooth segment to the fracture line is indicated to preserve the tooth	4 weeks S <sup>+</sup> , C <sup>++</sup> 6-8 weeks C <sup>++</sup> 4 months S <sup>++</sup> , C <sup>++</sup> 6 months C <sup>++</sup> 1 year C <sup>++</sup> 5 years C <sup>++</sup>	Positive response to pulp testing (false negative possible up to 3 months)     Signs of repair between fractured segments     Continue to next evaluation	Symptomatic Negative response to pulp testing (false negative possible up to 3 months) Extrusion of the coronal segment Radiolucency at the fracture line Clinical signs of periodontitis or abscess associated with the fracture line Endodontic therapy appropriate for stage of root development is indicated
Alveolar fracture	The fracture involves the alveolar bone and may extend to adjacent bone Segment mobility and dislocation with several teeth moving together are common findings An occlusal change because of misalignment the fractured alveolar segment is often noted Sensibility testing may or may not be positive	the middle third  Fracture lines may be located at any level, from the marginal bone to the root apex  In addition to the angulations and occlusal film, additional views such as a panoramic radiograph can be helpful in determining the course and position of the fracture lines	Reposition any displaced segment and then splint  Suture gingival laceration if present Stabilize the segment for 4 weeks	4 weeks S <sup>+</sup> , C <sup>++</sup> 6-8 weeks C <sup>++</sup> 4 months C <sup>++</sup> 6 months C <sup>++</sup> 1 year C <sup>++</sup> 5 years C <sup>++</sup>	Positive response to pulp testing (false negative possible up to 3 months)     No signs of apical periodontitis     Continue to next evaluation	Symptomatic     Negative     response to pulp     testing (false     negative possible     up to 3 months)     Signs of apical     periodontitis or     external     inflammatory root     resorption     Endodontic     therapy     appropriate for     stage of root     development is     indicated

2. Treatment guidel	ines for luxation injuries		Follow-up procedures for luxated permanent teeth	Favorable and unfavorable some, but no of the following <sup>2</sup>		
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome
Concussion	The tooth is tender to touch or tapping; it has not been displaced and does not have increased mobility Sensibility tests are likely to give positive results	No radiographic abnormalities	No treatment is needed     Monitor pulpal condition for at least 1 year	4 weeks C <sup>++</sup> 6-8 weeks C <sup>++</sup> 1 year C <sup>++</sup>	Asymptomatic     Positive response to pulp testing     False negative possible up to 3 months     Continuing root development in immature teeth     Intact lamina dura	Symptomatic     Negative response to pulp testing     False negative possible up to 3 months     No continuing roo development in immature teeth, signs of apical periodontitis     Endodontic therap appropriate for stage of root development is indicated
Subluxation	The tooth is tender to touch or tapping and has increased mobility; it has not been displaced Bleeding from gingival crevice may be noted Sensibility testing may be negative initially indicating transient pulpal damage  Monitor pulpal response until a definitive pulpal diagnosis can be made	Radiographic abnormalities are usually not found	Normally no treatment is needed; however, a flexible splint to stabilize the tooth for patient comfort can be used for up to 2 weeks	2 weeks S <sup>+</sup> , C <sup>++</sup> 4 weeks C <sup>++</sup> 6-8 weeks C <sup>++</sup> 6 months C <sup>++</sup> 1 year C <sup>++</sup>	Asymptomatic     Positive response to pulp testing     False negative possible up to 3 months     Continuing root development in immature teeth     Intact lamina dura	Symptomatic     Negative response to pulp testing     False negative possible up to 3 months     External inflammatory resorption
Extrusive luxation	The tooth appears elongated and is excessively mobile Sensibility tests will likely give negative results  The tooth appears elongated and is excessively mobile.  The tooth appears elongated and is excessively mobile.  The tooth appears elongated and is excessively mobile.	Increased periodontal ligament space apically	Reposition the tooth by gently re-inserting It into the tooth socket Stabilize the tooth for 2 weeks using a flexible splint In mature teeth where pulp necrosis is anticipated or if several signs and symptoms indicate that the pulp of mature or immature teeth became necrotic, root canal treatment is indicated	6 months C <sup>++</sup> 1 year C <sup>++</sup>	Asymptomatic     Clinical and radiographic signs of normal or healed periodontium     Positive response to pulp testing (false negative possible up to 3 months)     Marginal bone height corresponds to that seen radiographically after repositioning     Continuing root development in immature teeth	Symptoms and radiographic sign consistent with apical periodontiti Negative response to pulp testing (false negative possible up to 3 months) If breakdown of marginal bone, splint for an additional 3–4 weeks External inflammatory root resorption Endodontic therat appropriate for stage of root development is indicated

Treatment guidelines for luxation injuries				Follow-up procedures for luxated permanent teeth	Favorable and unfavorable outcomes include some, but not necessarily all, of the following <sup>2</sup>	
	Clinical findings	Radiographic findings	Treatment	Follow up	Favorable outcome	Unfavorable outcome
Lateral Luxation	The tooth is displaced, usually in a palatal/lingua or labial direction. It will be immobile and percussion usually gives a high, metallic (ankylotic) sound. Fracture of the alveolar process present. Sensibility tests will likely give negative results.	Il ligament space is best seen on eccentric or occlusal exposures	Reposition the tooth digitally or with forceps to disengage it from its bony lock and gently reposition it into its original location Stabilize the tooth for 4 weeks using a flexible splint Monitor the pulpal condition If the pulp becomes necrotic, root canal treatment is indicated to prevent root resorption	2 weeks S <sup>+</sup> , C <sup>++</sup> 4 weeks C <sup>++</sup> 6-8 weeks C <sup>++</sup> 6 months C <sup>++</sup> 1 year C <sup>++</sup> Yearly for 5 years C <sup>++</sup>	Asymptomatic     Clinical and radiographic signs of normal or healed periodontium     Positive response to pulp testing (false negative possible up to 3 months)     Marginal bone height corresponds to that seen radiographically after repositioning     Continuing root development in immature teeth	Symptoms and radiographic signs consistent with apical periodontitis     Negative response to pulp testing (false negative possible up to 3 months)     If breakdown of marginal bone, splint for an additional 3–4 weeks     External inflammatory root resorption or replacement resorptio     Endodontic therapy appropriate for stage of root development is indicated
Intrusive luxation	The tooth is displaced axially into the alveolar bone It is immobile, and percussion may give a high, metallic (ankylotic) sound Sensibility tests will likely give negative results	The periodontal ligament space may be absent from all or part of the root The cemento-enamel junction is located more apically in the intruded tooth than in adjacent non-injured teeth, at times even apical to the marginal bone level	Teeth with incomplete root formation  Allow eruption without intervention  If no movement within few weeks, initiate orthodontic repositioning  If tooth is intruded more than 7 mm, reposition surgically or orthodontically Teeth with complete root formation  Allow eruption without intervention if tooth intruded less than 3 mm. If no movement after 2–4 weeks, reposition surgically or orthodontically before ankylosis can develop  If tooth is intruded beyond 7 mm, reposition surgically or orthodontically before ankylosis can develop  If tooth is intruded beyond 7 mm, reposition surgically enercotic in teeth with complete root formation. Root canal therapy using a temporary filling with calcium hydroxide is recommended and treatment should begin 2–3 weeks after surgery  Once an intruded tooth has been repositioned surgically or orthodontically stabilize with a flexible splint for 4–8 weeks		Tooth in place or erupting Intact lamina dura No signs of resorption Continuing root development in immature teeth	Tooth locked in place/ankylotic tone to percussion Radiographic signs of apical periodontitis External inflammatory root resorption or replacement resorption Industrial Endodontic therapy appropriate for stage of root development is indicated

<sup>1</sup>For crown-fractured teeth with concomitant luxation injury, use the luxation follow-up schedule.
<sup>2</sup>Whenever there is evidence of external inflammatory root resorption, root canal therapy should be initiated immediately, with the use of calcium hydroxide as an intra-canal medication.

#### **Patient instructions**

Patient compliance with follow-up visits and home care contributes to better healing following a TDI. Both patients and parents of young patients should be advised regarding care of the injured tooth/teeth for optimal healing, prevention of further injury by avoidance of participation in contact sports, meticulous oral hygiene, and rinsing with an antibacterial such as chlorhexidine gluconate 0.1% alcohol free for 1–2 weeks.

#### Additional resources

Besides the general recommendations mentioned earlier, clinicians are encouraged to access the DTG, the journal Dental Traumatology, and other journals for information pertaining to treatment delay (37), intrusive luxations 38–47), root fractures (48–52), pulpal management of fractured and luxated teeth (34, 53–64, splinting (18, 39, 65–68), and antibiotics (69).

# Corrigendum

## Dent Traumatol 2012;28:499

In DiAngelis et al. (1), the following corrections should be made:

Under the heading 'Follow up' for both lateral luxation and intrusion, the first two time periods should be read as:

- 2 weeks, C++ (not 2 weeks S+, C++)
- 4 weeks S+, C++ (not 4 weeks C++)

This makes splint removal at 4 weeks consistent with what is recommended under

Under 'Treatment', 'Teeth with complete root formation', there should be an additional second bullet to read as:

• if tooth is intruded 3-7 mm, reposition surgically or orthodontically

The last word in the fourth bulleted sentence should be repositioning instead of

The authors would like to apologize for these errors.
